## PAXOS

Lecture C

---

PAXOS, SIMPLY

# CONSENSUS PROBLEM

- Consensus **impossible** to solve in asynchronous systems (FLP Proof)
  - Key to the Proof: It is impossible to distinguish a failed process from one that is just very very (very) slow. Hence the rest of the alive processes may stay ambivalent (forever) when it comes to deciding.
- But Consensus important since it maps to many important distributed computing problems
- Um, can't we just solve consensus?

# YES WE CAN!

- Paxos algorithm

- Most popular “consensus-solving” algorithm
- Does not solve consensus problem (which would be impossible, because we already proved that)
- But provides safety and eventual liveness
- A lot of systems use it
  - Zookeeper (Yahoo!), Google Chubby, and many other companies

- Paxos invented by? (take a guess)

# YES WE CAN!

- Paxos invented by Leslie Lamport
- Paxos provides safety and eventual liveness
  - Safety: Consensus is not violated
  - Eventual Liveness: If things go well sometime in the future (messages, failures, etc.), there is a good chance consensus will be reached. But there is no guarantee.
- FLP result still applies: Paxos is not *guaranteed* to reach Consensus (ever, or within any bounded time)

# POLITICAL SCIENCE 101, I.E., PAXOS GROKED

- Paxos has **rounds**; each round has a unique ballot id
- Rounds are asynchronous
  - Time synchronization not required
  - If you're in round  $j$  and hear a message from round  $j+1$ , abort everything and move over to round  $j+1$
  - Use timeouts; may be pessimistic
- Each round itself broken into phases (which are also asynchronous)
  - Phase 1: A leader is elected (**Election**)
  - Phase 2: Leader proposes a value, processes ack (**Bill**)
  - Phase 3: Leader **multicasts** final value (**Law**)

# PHASE 1 – ELECTION

- Potential leader chooses a unique ballot id, higher than anything seen so far
- Sends to all processes
- Processes wait, respond once to highest ballot id
  - If potential leader sees a higher ballot id, it can't be a leader
  - Paxos tolerant to multiple leaders, but we'll only discuss 1 leader case
  - Processes also log received ballot ID on disk
- If a process has in a previous round decided on a value  $v'$ , it includes value  $v'$  in its response
- If majority (i.e., quorum) respond OK then you are the leader
  - If no one has majority, start new round
- (If things go right) A round cannot have two leaders (why?)

# PHASE 2 – PROPOSAL (BILL)

- Leader sends proposed value  $v$  to all
  - use  $v=v'$  if some process already decided in a previous round and sent you its decided value  $v'$
- Recipient logs on disk; responds OK

# PHASE 3 – DECISION (**LAW**)

- If leader hears a majority of OKs, it lets everyone know of the decision
- Recipients receive decision, log it on disk

# WHICH IS THE POINT OF No-RETURN?

- That is, when is consensus reached in the system

# WHICH IS THE POINT OF No-RETURN?

- If/when a majority of processes hear proposed value and accept it (i.e., are about to/have respond(ed) with an OK!)
- Processes *may not know it yet*, but a decision has been made for the group
  - Even leader does not know it yet
- What if leader fails after that?
  - Keep having rounds until some round completes

# SAFETY

- If some round has a majority (i.e., quorum) hearing proposed value  $v'$  and accepting it (middle of Phase 2), then subsequently at each round either: 1) the round chooses  $v'$  as decision or 2) the round fails
- Proof:
  - Potential leader waits for majority of OKs in Phase 1
  - **At least one will contain  $v'$**  (because two majorities or quorums always intersect)
  - It will choose to send out  $v'$  in Phase 2
- Success requires a majority, and any two majority sets intersect

# WHAT COULD GO WRONG?

- Process fails
  - Majority does not include it
  - When process restarts, it uses log to retrieve a past decision (if any) and past-seen ballot ids. Tries to know of past decisions.
- Leader fails
  - Start another round
- Messages dropped
  - If too flaky, just start another round
- Note that anyone can start a round any time
- Protocol may never end – tough luck, buddy!
  - Impossibility result not violated
  - If things go well sometime in the future, consensus reached

# WHAT COULD GO WRONG?

- A lot more!
- This is a highly simplified view of Paxos.
- See Lamport's original paper:  
<http://research.microsoft.com/enus/um/people/lamport/pubs/paxosimple.pdf>

# SUMMARY

- Consensus is a very important problem
  - Equivalent to many important distributed computing problems that have to do with *reliability*
- Consensus is possible to solve in a synchronous system where message delays and processing delays are bounded
- Consensus is impossible to solve in an asynchronous system where these delays are unbounded
- Paxos protocol: widely used implementation of a safe, eventually-live consensus protocol for asynchronous systems
  - Paxos (or variants) used in Apache Zookeeper, Google's Chubby system, Active Disk Paxos, and many other cloud computing systems

# NEXT

- For the brave among you: the proof of Impossibility of Consensus (FLP Proof)
